

G. W. Gibbons

Carrollian Structures and the BMS and Conformal BMS Groups

The First Conference

of the Polish Society on Relativity

Spala

29 June -4 July 2014

June 30, 2014

This talk is based on three recent papers and one not so recent paper.

## Contents

- Galilei and Carroll groups as Kinematic groups obtained by contraction
- Isomorphism of Galilei and Carroll groups in  $1 + 1$  spacetime dimensions
- Carrollian and Newton-Cartan Structures
- Bargmann Structures

- Carrollian and Newton-Cartan Structures obtained from a Bargmann structure in one higher dimension: Duality as projection versus pull back.
- Carrollian Automorphisms and Conformal Automorphisms
- Isomorphism of Conformal Carroll and Conformal Galilei algebras in  $1 + 1$  spacetime dimensions
- BMS, and Newman-Unti groups as special cases
- Applications

The basic idea of all four papers is to look at **non-Einsteinian Relativity Principles** from an, albeit anachronistic, **Spacetime view point**

In our context a **Principle of Relativity** involves a notion of the **invariance of physical laws under passing to a moving frame** which we interpret as a **symmetry of some sort of spacetime structure**.

In effect we follow the path pioneered by Bacry and Levy-Leblond \* who found all algebras containing rotations, spatial and temporal translations and **boosts**. All may be regarded as Wigner-Inönü contractions † of the two De-Sitter groups.

Note that without boosts we would simply be classifying **Aristotelian spacetimes** which leads to Helmholtz's classification of congruence geometries ‡ .

\*H. Bacry and J. Levy-Leblond, Possible kinematics J. Math. Phys. **9** (1968) 1605.

†E. Inönü, E.P. Wigner (1953). "On the Contraction of Groups and Their Representations". Proc. Nat. Acad. Sci. 39 (6): 51024.

‡Über die Thatsachen, welche der Geometrie zu Grunde liegen, in Wissenschaftliche Abhandlungen, Volume II, Leipzig: Johann Ambrosius Barth, 618639. Originally published in the Nachrichten von der Königl. Gesellschaft der Wissenschaften zu Göttingen, No. 9 (3 June 1868).

The contractions are:

- Newton-Hooke  $\Lambda \rightarrow O, \quad c \rightarrow \infty, \quad c^2 \frac{\Lambda}{3}$  finite
- Poincaré  $\Lambda \rightarrow O, \quad c$  finite.
- Galilei  $\Lambda \rightarrow O, \quad c \rightarrow \infty.$
- Carroll  $\Lambda \rightarrow O, \quad c \rightarrow 0$

There is a certain **duality between the Galilei and Carroll groups**. In one the future light cone  $t > \frac{1}{c}|\mathbf{x}|$  expands to become a future half space  $t > 0$ . In the other it contracts to become a future half line  $t > 0, \mathbf{x} = 0$ . One allows instantaneous propagation, the other is **ultra-local** and forbids any propagation.

All kinematic groups have flat invariant **model space time** which allows a curved generalisation.

For Galilei this is Newton-Cartan spacetime with its degenerate co-metric  $g^{ij}$  whose kernel are co-normals of the absolute time slices

Carrollian spacetime. has a degenerate metric  $g_{ij}$  whose kernel is tangent to the absolute future \*.

\*To quote Mrs Thatcher: TINA, i.e. There is no alternative

Well, in our country," said Alice, still panting a little, "you'd generally get to somewhere else if you run very fast for a long time, as we've been doing."

A slow sort of country!" said the Queen. "Now, here, you see, it takes all the running you can do, to keep in the same place. If you want to get somewhere else, you must run at least twice as fast as that!"

For Galilei, boosts act as

$$(t, \mathbf{x}) \rightarrow (t, \mathbf{x} - \mathbf{v}t)$$

For Carroll, boosts act as

$$(s, \mathbf{x}) \rightarrow (s - \mathbf{b} \cdot \mathbf{x}, \mathbf{x})$$

where  $t$  is Galilean time and  $s$  is Carrollian time.

In 1+1 spacetime dimensions, Galileo and Carroll coincide as groups  
. since we may interchange Galilean space and with Carrollian time and

*vice versa*

Taking the limit  $c \uparrow \infty$  in the contra-variant Minkowski co- metric

$$-\frac{1}{c^2} \frac{\partial}{\partial t} \otimes \frac{\partial}{\partial t} + \delta^{ij} \frac{\partial}{\partial x^i} \frac{\partial}{\partial x^j}$$

motivates the definition of a **Newton-Cartan Spacetime** as a quadrupole  $\{N, \gamma, \theta, \nabla\}$  where  $N$  is a smooth  $d+1$  manifold ,  $\gamma$  a symmetric semi-positive definite contravariant 2-tensor of rank  $d$  with kernel the one-form  $\theta$  and  $\nabla$  a symmetric affine connection w.r.t. which  $\gamma$  and  $\theta$  are parallel.

Taking the limit  $c \uparrow \infty$  in the co-variant Minkowski metric

$$-c^2 dt^2 + \delta_{ij} dx^i dx^j$$

motivates the definition of a **Carrollian Spacetime** as a quadrupole  $\{C, g, \xi, \nabla\}$  where  $N$  is a smooth  $d + 1$  manifold ,  $g$  a symmetric semi-positive definite co-variant 2-tensor of rank  $d$  with kernel the vector field  $\xi$  and  $\nabla$  a symmetric affine connection w.r.t. which  $\xi$  and  $\nabla$  are parallel.

The standard flat case is  $C = \mathbb{R} \times \mathbb{R}^d$ ,  $g_{ij} = \delta_{ij}$ ,  $\xi = \frac{\partial}{\partial s}$ ,  $\Gamma_{\mu}{}^{\nu}{}_{\lambda} = 0$  where  $s$  is Carrollian time. The isometry group of the Carrollian metric contains

$$x^i \rightarrow x^i, \quad s \rightarrow s + f(x^i)$$

and so is infinite dimensional but if we require that the Carrollian automorphisms preserve the connection  $\nabla$  we obtain the standard finite dimensional Carroll group.

All the kinematic groups have a description in terms of Lorentzian geometry in 4+1 spacetime dimensions.

- Minkowski spacetime arises from a Kaluza-Klein reduction on a spacelike translation as shown by Kaluza and Klein.
- Newton-Cartan spacetime from a reduction on a null translation as shown by Duval and Kunzle.
- Carrollian spacetime arises as the pull-back to a null hyperplane.

Indeed given any null surface (like future null infinity)  $\mathcal{I}^+$  Carrollian structures come into play.

We define a **Bargmann Manifold** as a triple  $\{B, G, \xi\}$  where  $B$  is a  $(d+2)$  manifold,  $G$  a Lorentzian metric (i.e non-degenerate and signature  $(d+1, 1)$ ) and a null vector field  $\xi$  which is parallel w.r.t. the Levi-Civita connection of  $G$ . The standard flat Bargmann structure is given by  $B = \mathbb{R}^d \times \mathbb{R}^2$ ,  $\xi = \frac{\partial}{\partial s}$  with

$$G = \delta_{ij} dx^i dx^j + dt \otimes ds + ds \otimes dt$$

Not that *both*  $s$  and  $t$  are null coordinates.

The standard flat Newton-Cartan structure is obtained by **pushing forward** the flat Bargmann structure to the quotient or **lightlike shadow** or **null reduction**  $N = B/(\mathbb{R}\xi)$ . The Bargmann group consists of those isometries of  $B$  which preserve  $\xi$ . This is a central extension of the Galilei group, the centre being generated by  $\xi$ .

One may also obtain the central extension of the conformal Schroedinger group, the symmetry of the free Schroedinger equation as the those conformal transformations of  $d + 2$ -dimensional Minkowski spacetime which commute with the action of  $\mathbb{R}\xi$ .

Massless scalar field in  $\mathbb{E}^{d+1,1}$  is invariant under conformal transformations

$$2\frac{\partial^2\phi}{\partial t\partial s}\phi(s, t, x^i) + \nabla^2\phi = 0.$$

set

$$\xi\phi = -im\phi, \quad \phi = e^{-ims}\psi(t, x^i)$$

then

$$i\frac{\partial\psi}{\partial t} = -\frac{1}{2m}\nabla^2\psi.$$

The standard flat Carroll structure is obtained by **pulling back** the flat Bargmann structure to a **null hypersurface**  $t = \text{constant}$ . The Carroll group consists of these isometries of  $B$  which commute with the pull back.

Note, by a Lie-algebra co-homology argument it has been shown that the Carroll group admits no central extension.

A non-standard Carroll structure may be obtained by taking the product  $C = \mathbb{R} \times \Sigma_d$  where  $\Sigma_d$  with Riemann metric  $\hat{g}$  and  $g = \hat{g} \oplus 0 \times du^2$  and  $\xi = \frac{\partial}{\partial u}$ , where  $u$  is a coordinate on  $\mathbb{R}$ . For  $\nabla$  we *could* take the Levi-civita connection of  $\{\Sigma, \hat{g}\}$ .

For a general Carroll structure  $\{C, g, \xi \nabla\}$  we define the **Conformal Carroll group of level  $N$**  as consisting of diffeomorphisms  $a$  such that

$$a^* \hat{g} = \Omega^2 \hat{g}, \quad a_* \xi = \Omega^{-\frac{2}{N}} \xi$$

For the flat Carroll structure this has Killing vector fields

$$X = (\omega_{ij} x_j + \gamma_i (\chi - 2\kappa_i x_i) + \kappa_i x_j x_j) \frac{\partial}{\partial x_i} + \left( \frac{2}{N} (\chi - 2\kappa_j x_j) u + T(x_k) \right) \frac{\partial}{\partial u}$$

This is *infinite dimensional* because of the **super-translations**  $T(x_i)$  which have conformal weight  $= -\frac{2}{N}$ , i.e. are densities of weight  $\nu = -\frac{2}{Nd}$ . The quantity  $z = \frac{2}{N}$  is known as a **dynamical exponent**.

If  $N = 2$  ,  $z = 1$  and we have symmetry between the scaling of space and time.

If  $d = 1$ , using the isomorphism between the Carroll and Galilei algebras described above we obtain the **Conformal Galilei algebra**. **CGA** introduced by many people in a variety of contexts.

The **isometry group of the flat Carroll structure** is obtained by setting  $\Omega = 1$ . Its Lie algebra is also infinite dimensional, because of the supertanslations. Requiring that the connection is preserved reduces the Carroll Lie algebra to the standard finite dimensional case obtained by Levy-Lebond and Bacry.

For a general Carrollian structure , the Conformal Carroll group is generated by

$$X = Y + \left( \frac{\lambda}{N} + T(x) \right) \frac{\partial}{\partial u}$$

where  $Y$  is a conformal vector field of  $\{\Sigma, \hat{g}\}$

$$\mathcal{L}_Y g = \lambda g$$

generating

$$x \rightarrow \phi(x), \quad u \rightarrow \Omega^{\frac{2}{N}}(u + \alpha(x))$$

## Example

If  $\{\Sigma_d, \hat{g}\} = \{S^1, d\theta^2\}$  we get  $\text{Diff}(S^1)$  semi-direct product super translations of weight  $\nu = -\frac{2}{N}$  generated by the vector field

$$X = Y(\theta)\frac{\partial}{\partial\theta} + \left(\frac{2}{N}Y'(\theta) + T(\theta)\right)\frac{\partial}{\partial u}.$$

whose algebra is an extension of the **Witt** or **Virasoro** algebra.

## Example

If  $\{\Sigma_d, g\} = \{S^2, d\theta^2 + \sin^2\theta d\phi^2\}$  and  $N = 2$  we get

$$PSL(2, \mathbb{C}) \ltimes \mathcal{T}$$

where  $\mathcal{T}$  are half densities on  $S^2$  which is the **Bondi-Metzner-Sachs Group**

Which was originally discovered as the asymptotic symmetry group of an asymptotically flat four-dimensional spacetime. The BMS Group has an obvious generalisation to  $S^d$  for all  $d > 2$ . However this generalisation does not appear to coincide with the asymptotic symmetry group of an asymptotically flat spacetime of dimension greater than four.

We may weaken our requirement on the conformal Carroll group so that  $\alpha(x)$  only preserves the conformal class of the Carroll metric  $g$ . Since the vector field  $\xi$  spans the kernel of  $g$ ,  $\alpha$  is only required to preserve the *direction* of  $\xi$ . Thus its generating vector field  $X$  need only satisfy

$$\mathcal{L}_X \xi = \mu(x, u) \xi, \quad \Rightarrow X = Y + F(u, x) \frac{\partial}{\partial u} \quad (1)$$

where  $F(u, x)$  is an arbitrary function of *both*  $u$  and  $x$ , and  $Y$  is a conformal Killing field of the Riemannian manifold  $\{\Sigma_d, \hat{g}\}$

## Example

If  $\{\Sigma_d, \hat{g}\} = \{\Sigma_d, g\} = \{S^2, d\theta^2 + \sin^2 \theta d\phi^2\}$  we obtain the **Newman-Unti Group** which was introduced by these authors in the study of asymptotically flat four-dimensional spacetimes.

- Carrollian and BMS symmetries have a number of applications to various topics of current interest to string theorists and holography which was the original motivation for the work reported in this lecture.
- Using our enhanced understanding of the Carroll group We were able to construct Carrollian-invariant theories of electromagnetism.
- Using a method of Souriau we constructed theories of Carrollian massive and massless particles. One finds the former do not move, consistent with other view points.
- Perhaps the most intriguing is to **Schild or Null Strings**, that is strings whose two-dimensional world sheet carries a Carrollian metric, i.e. is a two-dimensional null surface. It turns out that Souriau's procedure for obtaining dynamical systems invariant under a group  $G$  applied to massless "particles" leads to Schild Strings.

Souriau's procedure starts with an **Evolution space**  $\{V, \sigma\}$  where  $\sigma$  is a closed 2-form,  $d\sigma = 0$ . By virtue of the closure of  $\sigma$  its kernel  $\ker(\sigma)$  defines a (i.e. continuous assignment of a vector sub-space  $\ker(\sigma) \subset TM$ ) which is *integrable*, i.e. for which  $A, B \in \ker(\sigma) \rightarrow [A, B] \in \ker(\sigma)$ . The space of leaves  $\{U, \sigma\}$  is thus a symplectic manifold called the **Space of Motions**, i.e. the space of histories of the system defined by  $\{V, \sigma\}$ .

For a Lie group  $G$  one may choose for  $V = G/H$  a co-adjoint orbit of  $G$  in  $\mathfrak{g}$  equipped with the so-called its **Kostant-Kirilov-Souriau 2-form**. For a spacetime group, such as the Carroll group we may also project the leaves defined by  $\ker(\text{Kostant - Kirilov - Souriau 2 - form})$  in the spacetime, (another coset).

If the projected orbits have dimension  $p + 1$  we have a p-brane. The case  $p = 0$  is a particle and if  $p = 1$  we have a string.

Cranking through this machinery we found that if  $G = \text{Carroll}$  we obtain a Schild String.
